

FMCG Multi-Country Sales Dataset Analysis

(Business Insights)

Document no.: 06

Pages: 03

Date: 7 September, 2026

6.1 Executive Summary

This project is an analysis of FMCG retail sales data to identify patterns in sales performance, product demand, promotional activity, store performance, inventory availability and supply-chain characteristics. The analysis combined SQL-based analytical investigation with an interactive Power BI dashboard to translate raw sales records into actionable business insights. The findings indicate that sales performance should not be evaluated solely through total revenue. Product mix, store performance, promotional activity, inventory availability and supplier lead times all contribute to operational performance.

6.2 Key Business Insights

1. Sales Performance

Sales trends were analyzed across 3-year timespan (year wise) to identify periods of stronger and weaker performance.

This indicates sales growth from 2021 to 2022 was 0.16%. Then again from 2022 to 2023, it went down by - 0.16%. Which means the business has actually a static phase (no growth) which may be because of no increase in demand and constant supply.

2. Product Performance

This graph shows top 10 products that contributed the most in overall business revenue & earning.

This means, these products should have top most priority in maintaining stock and reducing avg. delivery time to sustain the current static phase of the business. Failing to so will result in business under performance.

3. High Stock-out Alerts

Usually, it's not a bad thing for products that suffer stockout, especially when those products sell less/ has low demand. But from this finding, I saw that in these top 10 high stock-out products, some are high selling products that contribute significantly in overall business revenue.

So, it is mandatory to keep the running products under supervisory radar and keep backup stocks ready for emergency. Collaboration with suppliers is crucial.

4. Discount & Promo Sales

To my findings, I found it surprising that majority of revenue came from without any discounts/promo offers! Which is unusual in real business models.

About 90% of total sales came from without discounts, as well as promotional sales is only 10.4% of overall sales. However, my logical explanation of such scenario is that, the business is a wholesale-transport type model. That's why the dealers/suppliers don't care that much on discounts. Promotional activity may be associated with changes in sales volume or revenue, but observed relationships should not automatically be interpreted as causal effects.

5. Supplier & Lead-time performance

Longer lead times can increase the risk of inventory shortages if replenishment decisions are made too late. In my analysis, I grouped supply lead times based on markets (countries).

Average lead time in all 6 markets is almost the same (~6.5 days) which indicates the transportation and supply chain system is in close proximity relevant to each market. However, Suppliers with consistently high lead times should be monitored more closely, and replenishment planning should account for supplier-specific lead times.

6. Market & Channel Performance

Channel performance were analyzed with respect to markets to identify geographic differences. From my finding, performance varies across locations, meaning that a uniform strategy may not be optimal for every market.

High-performing channels like hypermarket, E-commerce should be examined for successful product mix, availability and promotional practices in their popular markets that could potentially be replicated in weaker locations.

6.3 Analytical Limitations

No causal inference: Observed relationships between discounts, promotions and sales do not establish causality.

No explicit business targets: The current analytical dataset does not provide validated management target values for metrics such as sales, stockout rate or profit. Therefore, target-versus-actual KPI analysis was not fabricated.

Historical analysis: The findings describe patterns in the available historical dataset and may not automatically predict future performance.

Dataset grain: The analysis is based on the available sales-record grain rather than individual customer-level transactions.
